Zop-level definitions

Kun: scala x.y.z.HelloWorld args Compile: scalac hello.scala println(""! + args.mkString("")) the compiled file HelloWorld.class in directory x/y/z/ def main(args: Array[String]): Unit = { package clause, e.g.: package x.y.z that places object HelloWorld { and object definitions, which may be preceded by a package x.y.z sequence of packagings, import clauses, and class // in file: hello.scala A compilation unit (here hello.scala) consists of a

Definitions and declarations

abstract member. Below defsAndDecl denotes a list of definitions and/or declarations. A definition binds a name to a value/implementation, while a declaration just introduces a name (and type) of an

Execution starts in method main.

Anonymous function value, "lambda". (a: Int, b: Int) => a + b d + b = fnI : (fnI : d)(fnI : b)bbe feb $\{E = 1, a = 3\}$ d + 6 = InI : (0 = InI : 0 , 0 = InI : 3 + 6Function f of type (Int, Int) => Int Function def f(a: Int, b: Int = a + b Initialized to default value, 0 for number types, null for AnyRef types. _ = fnI :x Jav **val** Seq(x, y) = Seq(e1, e2) Sequence pattern initialisation, x is assigned to e1 and y to e2. Tuple pattern initialisation, x is assigned to e1 and y to e2. $\mathbf{val}(\mathbf{x}, \mathbf{y}) = (\mathbf{el}, \mathbf{el})$ Multiple initialisations, x and y is initialised to the same value. val x, y = exprVariable x is assigned to expr. A var can be re-assigned. $\mathbf{var} \times \mathbf{x} = \mathbf{exbr}$ Explicit type annotation, expr: SomeType allowed after any expr. 0 = fnI :x 16v Yariable val x = expr Variable x is assigned to expr. A val can only be assigned once.

Makes name directly visible. Underscore imports all. import path.to.module.name Import Defines an alias A for the type in typeDef. Abstract if no typeDef. type A = typeDef class C extends D with T A class can only extend one normal class but mix in many traits using with. trait T { defsAndDecl } A trait is an abstract class without parameters. Can be used as an interface. Trait other case class goodies: equals, copy, hashcode, unapply, nice toString, companion object with apply factory. class C(parameters) { defsAndDecl } A template for objects, which are allocated with new. Class object Name { defsAndDecl } Singleton object auto-allocated when referenced the first time. Object def twice(block: => Unit) = { block; block } Call-by-name argument evaluated later. $^{-}$:($^{-}$:($^{-}$:) So is add All(Seq($^{-}$:) or add All(Seq($^{-}$:) or add All(Seq($^{-}$:): Partially applied function add(1) of add above, where inc is of type Int => Int Replacing a parameter list with a space and underscore gives the function itself as a value. val 9: (Int, Int) => Int = (a, b) => a + b Types can be omitted in lambda if inferable. Multiple parameter lists, apply: add(1)(2)Named arguments can be used in any order. Default arguments used if args omitted, f().

Restricts direct inheritance to classes in the same source file.	class definitions	pəzeəs
Delays initialization of val, initialized when first referenced.	snoitinñab Jav	γzel
Final members cannot be overridden, final classes cannot be extended.	aefinitions	Senit
Abstract classes cannot be instantiated (redundant for traits).	class definitions	abstract
Mandatory if overriding a concrete definition in a parent class.	definitions, declarations	override
Restricts access to subtypes and companion.	aefinitions	protected
Restricts access to directly enclosing class and its companion.	definitions, declarations	private
Restricts access to this instance only; also private[p] for package p.	definitions, declarations	private[this]

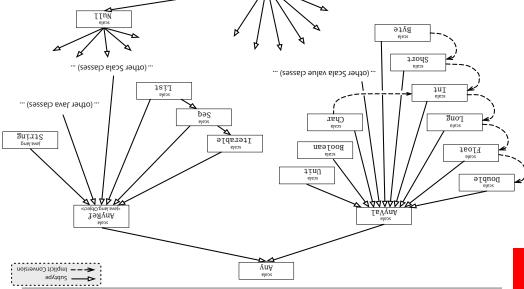

import path.to.{a, b => x, c => $_{-}$ } Import several names, b renamed to x, c not imported.

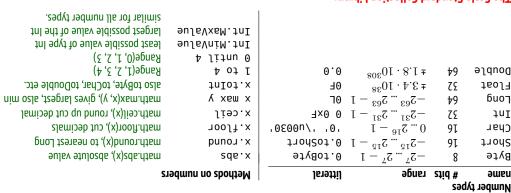

semantics

applies to

Төйірем

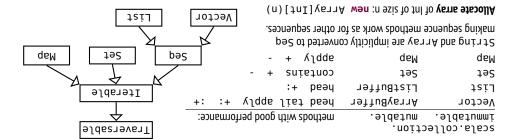

The Scala Type System

Nothing

The Scala Standard Collection Library

Concrete implementations of **Map** include HashMap and ListMap; collection.**SortedMap** is implemented by TreeMap. Concrete implementations of **Set** include HashSet, ListSet and BitSet; collection.**SortedSet** is implemented by TreeSet.

Special methods

```
class A(initX: Int = 0) {
                                               primary constructor: new A(1) or using default arg: new A()
  private var _x = initX
                                               private member only visible in A and its companion
                                               getter for private field x (name chosen to avoid clash with x)
  def x: Int = x
  def x_{-}(i: Int): Unit = \{ x = i \} special setter assignment syntax: val a = new A(1); a.x = 2
                                               companion object if same name and in same code file
object A {
                                               factory method makes new unnecessary: A.apply(1), A(1), A()
  def apply(i: Int = 0) = new A(i)
                                               private members can be accessed in companion
  val a = A(1).x
Getters and setters above are auto-generated by var in primary constructor:
                                                                       class A(var x: Int = 0)
With val in primary constructor only getter, no setter, is generated:
                                                                       class A(val x: Int = 0)
Private constructor e.g. to enforce use of factory in companion only: class A private (var x: Int = 0)
Instead of default arguments, an auxiliary constructor can be defined (less common): def this() = this(0)
                                                                    Special syntax for update and apply:
 class IntVec(private val xs: Array[Int]) {
                                                                    v(0) = 0 expanded to v.update(0,0)
   def update(i: Int, x: Int): Unit = { xs(i) = x }
                                                                    v(0) expanded to v.apply(0)
   def apply(i: Int): Int = xs(i)
                                                                    where val v = new IntVec(Array(1,2,3))
```

Expressions

2-tuple type

```
literals
       0 0L 0.0 "0" '0' true false
block
       { expr1: ...: exprN }
        if (cond) expr1 else expr2
        expr match caseClauses
match
        for (x < -xs) expr
vield
        for (x <- xs) vield expr
        while (cond) expr
while
do while do expr while (cond)
throw
        throw new Exception("Bang!")
        try expr catch pf
try
```

Basic types e.g. Int. Long. Double. String. Char. Boolean The value of a block is the value of its last expression Value is expr1 if cond is true, expr2 if false (else is optional) Matches expr against each case clause, see pattern matching. Loop for each x in xs, x visible in expr, type Unit Yeilds a sequence with elems of expr for each x in xs Loop expr while cond is true, type Unit Do expr at least once, then loop while cond is true, type Unit Throws an exception that halts execution if not in try catch Evaluate partial function pf if exception in expr, where pf e.g.:

```
{case e: Exception => someBackupValue}
Evaluation order
                    (1 + 2) * 3 parenthesis control order
Method application
                          1.+(2) call method + on object 1
Operator notation
                           1 + 2 same as 1.+(2)
Conjunction
                        c1 && c2 true if both c1 and c2 true
Disiunction
                        c1 | | c2 true if c1 or c2 true
                                ! c logical not, false if c is true
Negation
Function application f(1, 2, 3) same as f.apply(1,2,3)
                     x => x + 1 anonymous function, "lambda"
Function literal
Object creation
                     new C(1.2) from class C with arguments 1.2
Self reference
                             this refers to the object being defined
Supertype reference
                         super.m refers to member m of supertype
Non-referable reference
                             null refers to null object of type Null
Assignment operator
                          x += 1 expanded to x = x + 1
                          x -= 1 works for any op ending with =
Empty tuple, unit value
                                () of type Unit, similar to Java void
                          x -= 1 works for any op ending with =
2-tuple value
                  (1, "hello") same as new Tuple2(1, "hello")
```

(Int, String) same as Tuple2[Int, String]

etc. until Tuple22

Precedence of operators beginning with:

all letters lowest + -* / % other special chars hiahest

Integer division and reminder:

a / b no decimals if a, b Int, Short, Byte a % b fulfills: (a / b) * b + (a % b) == a

Pattern matching, type tests and extractors

```
expr is matched against patterns from top until match found, yielding the expression after =>
                                         literal pattern matches any value equal (in terms of ==) to the literal
  case "hello" => expr
  case x: C => expr typed variable pattern matches all instances of C, binding variable x to the instance
  case C(x, y, z) = \exp r constructor pattern matches values of the form C(x, y, z), args bound to x,y,z
  case (x, y, z) = \exp r tuple pattern matches tuple values, alias for constructor pattern Tuple 3(x, y, z)
                                  sequence extractor patterns matches head and tail, also x +: y +: z +: xs etc.
  case x +: xs => expr
                                           matches if at least one pattern alternative p1, p2 ... or pN matches
  case p1 | ... | pN => expr
  case x@pattern => expr
                                      a pattern binders with the @ sign binds a variable to (part of) a pattern
  case x => expr untyped variable pattern matches any value, typical "catch all" at bottom: case _ =>
                   Pattern matching on direct subtypes of a sealed class is checked if exhaustive by the compiler
Matching with typed variable pattern x match { case a: Int => a; case _ => 0} is preferred over
explicit isInstanceOf tests and casts: if (x.isInstanceOf[Int]) x.asInstanceOf[Int] else 0
The unapply method can be used in extractor pattern matching (to avoid extra class & instance), e.g.:
object Host {
                                                                                       Extractor object
  def unapply(s: String): Option[String] =
                                                                            extractor must return Option
     if (!s.startsWith("http://")) None
                                                                         None gives no match in patterns
     else s.stripPrefix("http://").split('/').headOption
                                                                            Some(x) matches in patterns
                                                        Extractor pattern leads to a call to Host.unapply(str)
str match { case Host(name) => ... }
Generic classes and methods
class Box[T](val x: T){
                                     a generic class Box with a type parameter T, allowing x to be of any type
  def pairedWith[U](v: U): (T, U) = (x, v)
                                                                 a generic method with type parameter U
                                     T is bound to the type of x, U is free in pairedWith, so y can be of any type
                                     same as (with explicit type parameters): val b: Box[Int] = new Box[Int](0)
val b = new Box(0)
val p = b.pairedWith(new Box("zero"))
                                                                     the type of p is (Box[Int], Box[String])
Generic types are erased before JVM runtime except for Array, so a reflect.ClassTag is needed when constructing arrays
from generic type parameters: def mkArray[A:reflect.ClassTag](a: A) = Array[A](a)
scala.{Option, Some, None}, scala.util.{Try, Success, Failure}
Option[T] is like a collection with zero or one element. Some[T] and None are subtypes of Option.
val opt: Option[String] = if (math.random > 0.9) Some("bingo") else None
opt.getOrElse(expr) x: T if opt == Some[T](x) else expr
opt.map(x \Rightarrow \dots) apply x \Rightarrow \dots to x if opt is Some(x) else None
                           x: T if Some(T)(x) else throws NoSuchElementException
opt.get
opt match { case Some(x) => expr1; case None => expr2 } expr1 if Some(x) else expr2
Other collection-like methods on Option: foreach, isEmpty, filter, toVector, ..., on Try: map, foreach, toOption, ...
Try[T] is like a collection with Success[T] or Failure[E]. import scala.util.{Try, Success, Failure}
Try{ ...: expr1 }.get0rElse(expr2) evaluates to expr1 if successful or expr2 if exception
Try{...; expr1}.recover{ case e: Throwable => expr2 } expr2 if exception else Success(expr1)
Trv(1/0) match {case Success(x) => x: case Failure(e) => 0} e here ArithmeticException
Reading/writing from file, and standard in/out:
Read string of lines from file (from File gives Buffered Source, getLines gives Iterator[String]; also from URL):
val s = scala.io.Source.fromFile("f.txt", "UTF-8").getLines.mkString("\n")
```

Read string from **standard in** (prompt string is optional) using readLine; **write** to **standard out** using println:

Write string to file after import java.nio.file.{Path, Paths, Files}; import java.nio.charset.StandardCharsets.UTF 8

val s = scala.io.StdIn.readLine("prompt"); println("you wrote" + s)

Files.write(Paths.get(fileName), data.getBytes(UTF_8))

def save(fileName: String, data: String): Path =

Scala

Strings

Scala

8(8)

Methods in trait Traversable[A]

	Inua Idaa	יין בייול בשני מוני בעום בעם ליים לביים מוב מני ספונים ויים
Make string:	xs mkString (start, sep, end)	A string with all elements of xs between separators sep enclosed in strings start and end; start, sep, end are all optional.
	xsm.ex nim.ex	which must be numeric.
	xs.sum xs.product	Calculation of the sum/product/min/max of the elements of xs,
	xs reduceRight op	with first element instead of z.
	xs reduceLeft op	Similar to foldLeft/foldRight, but xs must be non-empty, starting
	xs.foldRight(x)	going left to right (or right to left) starting with z.
Folds:	. (qo)(z)theldle	Apply binary operation op between successive elements of xs,
	xs conuf b	An Int with the number of elements in xs that satisfy p.
	g słsise sx	Returns true if p holds for some element of xs.
:snoitibno	d Jisnot ex	Returns true if p holds for all elements of xs.
	λ groupBy f	Partition xs into a map of collections according to f.
	xs partition p	Split xs by p into the pair (xs filter p, xs.filterNot p)
	d ueds sx	Split xs by p into the pair (xs takeWhile p, xs.dropWhile p).
	n ታAjilqe ex	Split xs at n returning the pair (xs take n, xs drop n).
	xs filterNot p	Those elements of xs that do not satisfy the predicate p.
	xs filter p	Those elements of xs that satisfy the predicate p.
	xs dropWhile p	Without the longest prefix of elements that all satisfy p.
	xs takeWhile p	The longest prefix of elements all satisfying p.
	xs drop n	The rest of the collection except xs take n.
	xs take n	The first n elements (or some n elements, if order undefined).
	xs slice (from, to)	The elements in from index from until (not including) to.
Subparts:	Jini.ex JieJ.ex	The rest of the collection except xs.head or xs.last.
	q bnil ex	An option with the first element satisfying p, or None.
	noilq01ss1.ex	defined) in an option value, or None if xs is empty.
	noijqObeəd.ex	The first/last element of xs (or some element, if no order is
Retrieval:	tsel.ex bead.ex	The first/last element of xs (or some elem, if order undefined).
	9ziz.ex	Returns an Int with the number of elements in xs.
	xs.nonEmpty	Returns true if the collection xs has at least one element.
:ołni əsič	γjqm∃si.ex	Returns true if the collection xs is empty.
	(u 's	at index s (last two arguments are optional). Return type Unit.
	xs copyToArray (arr,	Copies at most n elements of the collection to array arr starting
сору:	xs copyToBuffer buf	Copies all elements of xs to buffer buf. Return type Unit.
	deMot	Converts a collection of key/value pairs to a map.
	19201	Converts the collection to a set; duplicates removed.
	toBuffer toArray	matches the demanded type.
Сопуегt:	toVector toList toSeq	Converts a collection. Unchanged if the run-time type already
		st for which it is defined (undefined ignored).
	xs collect pf	The collection obtained by applying the pf to every element in
		tion) to all elements in xs and concatenating the results.
	l qeMjejl ex	A collection obtained by applying f (which must return a collec-
:deM	1 qsm ex	A collection formed by applying f to every element in xs.
:bbA	sk ++ sx	A collection with xs followed by ys.
Traverse:	t doreach f	Executes f for every element of xs. Return type Unit.
JadW	agasU	Explanation f is a function, pf is a partial funct., p is a predicate.

Strings are implictly treated as Seq[Char] so all Seq methods also works. Some methods below are from Java.lang.String and some methods are implicitly added from StringOps, etc.

```
Removes leading and trailing white space.
                                                                                               minj.z
                          Converts all characters to upper case.
                                                                                     s.toUpperCase
                          Converts all characters to lower case.
                                                                                      s.toLowerCase
                                Converts a number to a String.
                                                                   42.toString 42.0.toString
        Parses s as an Int or Double etc. May throw an exception.
                                                               s.toInt s.toDouble s.toFloat
               Returns a substring of s from index i to index j-1.
                                                                                 s.substring(i, j)
          Returns a substring of s with all charcters from index i.
                                                                                     (i)gnirisdus.a
 Strips leading white space followed by I from each line in string.
                                                                                     s.stripMargin
                            True if string s begins with string t.
                                                                                   s.startsWith(t)
Returns an array of strings split at every occurance of charachter c.
                                                                                          s.split(c)
                       Replace all occurances of s1 with s2 in s.
                                                                s.replaceAllLiterally(s1, s2)
                              True if string s ends with string t.
                                                                                      s.endsWith(t)
                                                                       s.compareToIgnoreCase(t)
                 Similar to compateTo but not sensitive to case.
        Returns x where x < 0 if s < t, x > 0 if s > t, x is 0 if s = t
                                                                                    s.compareTo(t)
   Returns this string with first character converted to upper case.
                                                                                       s.capitalize
                                                                s(i) s apply i s.charAt(i)
                              Returns the character at index i.

Reserved words

These 40 words and 10 symbols have special meaning and cannot be used as identifiers in Scala.

type val var while with yield -> <= = : package private protected return sealed super this throw trait try true forSome if implicit import lazy macro match new null object override abstract case catch class def do else extends false final finally for

Methods in trait Iterable[A]

What	Usage	Explanation
Iterators:	val it = xs.iterator	An iterator it of type Iterator that yields each element one
		<pre>by one: while (it.hasNext) f(it.next)</pre>
	xs grouped size	An iterator yielding fixed-sized chunks of this collection.
	xs sliding size	An iterator yielding a sliding fixed-sized window of elements.
Subparts:	xs takeRight n	Similar to take and drop in Traversable but takes/drops
	xs dropRight n	the last n elements (or any n elements if the order is undefined).
Zippers:	xs zip ys	An iterable of pairs of corresponding elements from xs and ys.
	xs zipAll (ys, x, y)	Similar to zip, but the shorter sequence is extended to match
		the longer one by appending elements x or y.
	xs.zipWithIndex	An iterable of pairs of elements from xs with their indices.
Compare:	xs sameElements ys	True if xs and ys contain the same elements in the same order.

Methods in trait Seq[A]

	vs(i) vs apply i	The element of xs at index i.
Indexing and size:	xs(i) xs apply i xs.length	Length of sequence. Same as size in Traversable.
aliu Size.	xs.tength xs.indices	Returns a Range extending from 0 to xs.length - 1.
	xs isDefinedAt i	True if i is contained in xs.indices.
1. 1.	xs lengthCompare n	Returns -1 if xs is shorter than n, +1 if it is longer, else 0.
Index	xs index0f x	The index of the first element in xs equal to x.
search:	xs lastIndexOf x	The index of the last element in xs equal to x.
	xs indexOfSlice ys	The (last) index of xs such that successive elements starting
	xs lastIndexOfSlice ys	from that index form the sequence ys.
	xs indexWhere p	The index of the first element in xs that satisfies p.
	xs segmentLength (p, i)	The length of the longest uninterrupted segment of elements in xs, starting with xs(i), that all satisfy the predicate p.
	xs prefixLength p	Same as xs.segmentLength(p, 0)
Add:	x +: xs	Prepend/Append x to xs. Colon on the collection side.
	xs padTo (len, x)	Append the value x to xs until length len is reached.
Update:	xs patch (i, ys, r)	A copy of xs with r elements of xs replaced by ys starting at i.
	xs updated (i, x)	A copy of xs with the element at index i replaced by x.
	xs(i) = x	Only available for mutable sequences. Changes the element of
	xs.update(i, x)	xs at index i to x. Return type Unit.
Sort:	xs.sorted	A new Seq[A] sorted using implicitly available ordering of A.
	xs sortWith lt	A new $Seq[A]$ sorted using less than lt: $(A, A) \Rightarrow$ Boolean.
By:	xs sortBy f	A new Seq[A] sorted/minimized/maximized by implicitly avail-
	xs maxBy f xs minBy f	able ordering of B after applying f: A => B to each element.
Reverse:	xs.reverse	A new sequence with the elements of xs in reverse order.
	xs.reverseIterator	An iterator yielding all the elements of xs in reverse order.
	xs reverseMap f	Similar to map in Traversable, but in reverse order.
Tests:	xs startsWith ys	True if xs starts with sequence ys.
	xs endsWith ys	True if xs ends with sequence ys.
	xs contains x	True if xs has an element equal to x.
	xs containsSlice ys	True if xs has a contiguous subsequence equal to ys
	(xs corresponds ys)(p)	True if corresponding elements satisfy the binary predicate p.
Subparts:	xs intersect ys	The intersection of xs and ys, preserving element order.
. F	xs diff ys	The difference of xs and ys, preserving element order.
	xs union ys	Same as xs ++ ys in Traversable.
	xs.distinct	A subsequence of xs that contains no duplicated element.

Methods in trait Set[A]

xs(x) xs apply x	True if x is a member of xs. Also: xs contains x
xs subsetOf ys	True if ys is a subset of xs.
xs + x $xs - xxs + (x, y, z)$ $xs - (x, y, z)$	Returns a new set including/excluding elements. Addition/subtraction can be applied to many arguments.
xs intersect ys	A new set with elements in both xs and ys. Also: &
xs union ys	A new set with elements in either xs or ys or both. Also:
xs diff ys	A new set with elements in xs that are not in ys. Also: &~

Scala

Additional mutation methods in trait mutable. Set[A]

xs += x xs += (x, y,	xs -= x z) xs -= (x, y, z)	Returns the same set with included/excluded elements. Addition/subtraction can be applied to many arguments.
xs ++= ys		Adds all elements in ys to set xs and returns xs itself.
xs add x		Adds element x to xs and returns true if x was in xs, else false.
xs remove x		Removes x from xs and returns true if x was in xs, else false.
xs retain p		Keeps only those elements in xs that satisfy predicate p.
xs.clear		Removes all elements from xs. Return type Unit.
xs(x) = b	xs.update(x, b)	If b is true, adds x to xs, else removes x. Return type Unit.
xs.clone		Returns a new mutable set with the same elements as xs.

Methods in trait Map[K, V]

ms get k	The value associated with key k an option, None if not found.
ms(k) ms apply k	The value associated with key k, or exception if not found.
ms getOrElse (k, d)	The value associated with key k in map ms, or d if not found.
ms isDefinedAt k	True if ms contains a mapping for key k. Also: ms.contains(k)
ms + (k -> v) ms + ((k, v))	The map containing all mappings of ms as well as the mapping
ms updated (k, v)	$k \rightarrow v$ from key k to value v . Also: $ms + (k \rightarrow v, l \rightarrow w)$
ms - k	Excluding any mapping of key k. Also: ms - (k, l, m)
ms ++ ks ms ks	The mappings of ms with the mappings of ks added/removed.
ms.keys ms.values ms.keySet	An Iterable/Set containing each key/value in ms.
ms.mapValues	A new Map obtained by applying f to values.

Additional mutation methods in trait mutable.Map[K, V]

ms(k) = v $ms.upda$	ate(k, v)	Adds mapping k to v, overwriting any previous mapping of k.
ms += (k -> v)	ms -= k	Adds/Removes mappings. Also vid several arguments.
ms put (k, v) ms	s remove k	Adds/removes mapping; returns previous value of k as an option.
ms retain p		Keeps only mappings that have a key satisfying predicate p.
ms.clear		Removes all mappings from ms.
ms transform f		Transforms all associated values in map ms with function f.
ms.clone		Returns a new mutable map with the same mappings as ms.

Factory examples:

```
Vector(0, 0, 0) same as Vector.fill(3)(0)
collection.mutable.Set.empty[Int] same as collection.mutable.Set[Int]()
Map("se" -> "Sweden", "nk" -> "Norway") same as Map(("se", "Sweden"), ("nk", "Norway"))
Array.ofDim[Int](3,2) gives Array(Array(0, 0), Array(0, 0), Array(0, 0)) same as
Array.fill(3,2)(0); Vector.iterate(1.2, 3)(_{-} + 0.5) gives Vector(1.2, 1.7, 2.2)
Vector.tabulate(3)("s" + _) gives Vector("s0", "s1", "s2")
```

etiskt uttryck (x + 2) * i / 2 + i % 2	för heltal är / heltalsdivision, % "rest"

```
String nextLine();
                     läser resten av raden
               också hasNextDouble(), ...
                                                             boolean hasNextInt();
      nästa heltal; också nextDouble(), ...
                                                                      int nextint();
                                                               boolean hasNext();
        ger true om det finns mer att läsa
                                                                      String next();
   läser nästa sträng fram till whitespace
                     laser från strängen s
                                                                 Scanner(String s);
                                                                   Scanner(File f);
          läser från filen f, ofta System.in
                                                                                                  Scanner
         double-tal i intervallet [0.0, 1.0)
                                                              double nextDouble();
                 heltal i intervallet [0, n)
                                                                 int nextlnt(int n);
             med bestämt slumptalsfrö
                                                               Random(long seed);
                                                                        Random();
skapar "slumpmässig" slumptalsgenerator
                                                                                                 Random
```

Filer, import java.io.File/FileMotFoundException/PrintWriter

```
Läsa från fil inte finns. Sedan Läser man "som vanligt" från scannern (nextlnt och liknande).

Skriva till fil Skapa en PrintWriter med new PrintWriter(new File(filename)), Ger FileNotFoundException om filen inte kan skapas. Sedan skriver man "som vanligt" på PrintWriter-objektet (println och liknande).

Scanner scan = null;

Scanner scan = null;

Scanner scan = null;

Scanner scan = null;

Scanner scan = new Scanner(new File("indata.txt"));

Scan = new Scanner(new File("indata.txt"));

Specialtecken

Några tecken måste skrivas på ett speciellt sätt när de används i teckenkonstanter:
```

```
/n ny rad, radframmatningstecken (ng. tab)
/t bakåtsnedstreck: / (eng. backslash)
/; apostrof: '

papostrof: '

papostrof: '
```

Reserverade ord

Medan 50 ord kan ej användas som identifierare i Java. Orden **goto** och **const** är reserverade men används ej.

abstract assert boolean break byte case catch char class const continue default do double else enum extends final finally float for goto if implements import instanceof int interface long native new package private protected public return short static strictfp super switch synchronized this throw throws transient try void volatile while

Deklarationer

Allmänt	<pre>[<protection>] [static] [final] <type> name1, name2,;</type></protection></pre>	
<type></type>	byte short int long float double boolean char Classname	
<pre><pre><pre><pre>o</pre></pre></pre></pre>	public private protected	för attribut och metoder i klasser (paketskydd om inget anges)
Startvärde	int x = 5;	startvärde bör alltid anges
Konstant	final int N = 20;	konstantnamn med stora bokstäver
Array	<type>[] vname = new <type>[10];</type></type>	deklarerar och skapar array
Matris	<type>[][] m = new <type>[4][5];</type></type>	// deklarerar och skapar 4x5 matrisen m

Klasser

```
Deklaration
                      [public] [abstract] class Classname
                          [ extends Classname1 ] [ implements Interface1, Interface2, ... ] {
                         <deklaration av attribut>
                         <deklaration av konstruktorer>
                         <deklaration av metoder>
Attribut
                     Som vanliga deklarationer. Attribut får implicita startvärden, 0, 0.0, false, null.
Konstruktor
                     prot> Classname(param, ...) {
                                                            Parametrarna är de parametrar som ges vid
                                                            new Classname(...). Satserna ska ge
                         stmt; ...
                                                            attributen startvärden
                                                            om typen inte är void måste en return-
Metod
                     stmt; ...
                                                            sats exekveras i metoden
Huvudprogram
                     public static void main(String[] args) { ... }
Abstrakt metod
                     Som vanlig metod, men abstract före typnamnet och \{\ldots\} ersätts med semikolon. Metoden
                     måste implementeras i subklasserna.
```

Standardklasser, java lang, behöver inte importeras

Object	Superklass till alla klasser.	
	<pre>boolean equals(Object other); int hashCode(); String toString();</pre>	ger true om objektet är lika med other ger objektets hashkod ger en läsbar representation av objektet
Math	Statiska konstanter Math.Pl och Math.E. Metoderna är statiska (anropas med t ex Math.round(x)):	
	long round(double x); int abs(int x); double hypot(double x, double y); double sin(double x); double exp(double x); double pow(double x, double y); double log(double x); double sqrt(double x); double toRadians(double deg);	avrundning, även float \to int $ x $, även double, $\sqrt{x^2+y^2} \sin x$, liknande: cos, tan, asin, acos, atan $e^x \ x^y \ \ln x \ \sqrt{x} \ deg \cdot \pi/180$
System	void System.out.print(String s); void System.out.println(String s); void System.exit(int status); Parametern till print och println kan v	skriv ut strängen s som print men avsluta med ny rad avsluta exekveringen, status != 0 om fel rara av godtycklig typ: int, double,

Wrapperklasser För varje datatyp finns en wrapperklass: char \rightarrow Character, int \rightarrow Integer, double \rightarrow Double, ...

Statiska konstanter MIN VALUE och MAX VALUE i klassen Integer ger minsta respektive största heltalsvärde. För klassen Double ger MIN VALUE minsta flyttalet som är större än noll.

Exempel med klassen Integer:

Integer(int value); skapar ett objekt som innehåller value

tar reda på värdet int intValue();

String Teckensträngar där tecknen inte kan ändras. "asdf" är ett String-objekt. s1 + s2 för att konkatenera

två strängar. StringIndexOutOfBoundsException om någon position är fel.

int lenath(): antalet tecken

char charAt(int i): tecknet på plats i. 0..length()-1

boolean equals(String s); jämför innehållet (s1 == s2 fungerar inte) int compareTo(String s): < 0 om mindre. = 0 om lika. > 0 om större

int indexOf(char ch): index för ch. -1 om inte finns

int indexOf(char ch, int from); som indexOf men börjar leta på plats from

String substring(int first, int last); kopia av tecknen first..last-1 String[] split(String delim); ger array med "ord" (ord är följder av tecken åtskilda med tecknen i delim)

Konvertering mellan standardtyp och String (exempel med int, liknande för andra typer):

String.valueOf(int x); $x = 1234 \rightarrow "1234"$

Integer.parseInt(String s); s = "1234" \rightarrow 1234, NumberFormat-

Exception om s innehåller felaktiga tecken

StringBuilder Modifierbara teckensträngar. length och charAt som String, plus:

> StringBuilder(String s); StringBuilder med samma innehåll som s

void setCharAt(int i. char ch): ändrar tecknet på plats i till ch

lägger till s, även andra typer: int, char, ... StringBuilder append(String s);

StringBuilder insert(int i, String s); lägger in s med början på plats i StringBuilder deleteCharAt(int i): tar bort tecknet på plats i String toString(); skapar kopia som String-objekt

Standardklasser, import java.util.Classname

List

List<E> är ett gränssnitt som beskriver listor med objekt av parameterklassen E. Man kan lägga in värden av standardtyperna genom att kapsla in dem, till exempel int i Integer-objekt. Gränssnittet implementeras av klasserna ArrayList<E> och LinkedList<E>, som har samma operationer. Man ska inte använda operationerna som har en position som parameter på en LinkedList (i stället en iterator). IndexOutOfBoundsException om någon position är fel.

För att operationerna contains, indexOf och remove(Object) ska fungera måste klassen E överskugga funktionen equals(Object). Integer och de andra wrapperklasserna gör det.

ArrayList LinkedList ArrayList<E>(); skapar tom lista LinkedList<E>(): skapar tom lista int size(); antalet element boolean isEmpty(); ger true om listan är tom

E get(int i); tar reda på elementet på plats i int indexOf(Object obj); index för obj. -1 om inte finns boolean contains(Object obj); ger true om obj finns i listan

void add(E obj); lägger in obj sist, efter existerande element

void add(int i, E obj); lägger in obj på plats i (efterföljande

element flyttas)

E set(int i, E obi); ersätter elementet på plats i med obj E remove(int i); tar bort elementet på plats i (efter-

följande element flyttas)

boolean remove(Object obj): tar bort objektet obj, om det finns void clear(): tar bort alla element i listan
